

Supplemental Methods

Mice

All mice were kept in a light-controlled environment with a 12:12 hour light-dark cycle and free access to standard mice chow and water. The WT and MMP-9 null colonies were bred in-house and maintained in the same room.

WT and MMP-9 null mice were each divided into one of 5 groups, with at least n=3 male and 3 female mice in each group. The groups were day (d) 0 no MI naïve controls, MI with saline, MI with Aliskiren (A, 50mg/kg/d), MI with Valsartan (V, 40mg/kg/d), and MI with Aliskiren and Valsartan (A+V). The exact sample sizes were: for WT, saline was 24, A was 23, V was 28, and A+V was 26; for Null, saline was 15, A was 22, V was 21, and A+V was 23. All mice enrolled in the study were used for the survival analysis.

MI was induced by permanently ligating the left anterior descending coronary artery as previously described.¹ The mice were anesthetized with 1-2% isoflurane in a 100% oxygen mix, intubated, and ventilated with a standard rodent ventilator (Harvard Ventilator). At 3 h post-MI, MI was confirmed by echocardiography, and the drug treatments were initiated by inserting an osmotic pump in the subcutaneous space between the scapula (Alzet® Model 2004, Durect Corporation, Cupertino, CA). Groups were randomized, with one individual (JZ) allocating mice, before the surgeries were performed, to one of the treatment groups. All other individuals were blinded to treatment groups throughout the analyses. The MI mice were all sacrificed at 28 d after MI, and genotypes were confirmed by tail genotyping.

Blood Pressure Measurement

Blood pressure measurements were made by tail cuff plethysmography, as described previously.² To ensure accuracy and reproducibility, each mouse was trained for 3-5 days prior to the experiment. Conscious unanesthetized mice were placed on the specimen platform of the MC4000 Multi-Channel Blood Pressure Analysis System (Hatteras Instruments, Inc. Cary, NC 27514), and their tails were placed through tail cuffs and secured in place with tape. Following a 15 min warm-up period, 5 preliminary cycles were performed to allow the mice to adjust to the inflating cuff. For each mouse, 10 cycles were acquired and averaged. Measurements were taken at baseline and at 28 days post-MI.

Echocardiography

Transthoracic echocardiography was performed using the Vevo 770 system (VisualSonics) with a 30-MHz image transducer. Mice were anesthetized with 0.5-2% isoflurane in a 100% oxygen mix. Electrocardiogram, heart rate, and body temperature were monitored throughout the imaging procedure, and heart rates were maintained at a minimum of 400 bpm. Volume measurements were taken from the parasternal long axis B-mode view. For each parameter, 3 images from consecutive cardiac cycles were measured and averaged.^{2, 3} Because this study was not powered to detect differences between sexes, we normalized for potential effects due to differences in body size between sexes. To normalize, the individual mouse echocardiography volume data and hypertrophy index were normalized to the respective body weight, multiplied by 100, and averaged.

Tissue Collection

Mice were sacrificed at 28 days post-MI under 2% isoflurane in a 100% oxygen mix.⁴ A control group of no MI (day 0) control mice were also sacrificed for comparison of naïve hearts. To arrest the heart in diastole, the heart was flushed with cardioplegic solution.⁵ LV tissue was separated from the right ventricle, weighed, and cut into 3 transverse sections and stained with 2,3,5-triphenyltetrazolium chloride (Sigma) for infarct area measurements. In each LV sample, the infarct (LVI) and remote (LVC) regions were separated and individually snap frozen for mRNA analysis (qRT-PCR arrays) or immunoblotting. The mid LV section was fixed in zinc-formalin for histology.⁶ The tibia was measured for normalization of LV mass.

Immunohistochemistry

Paraffin embedded samples were sectioned at 5 µm. One set of sections was stained with picrosirius red by incubating the slides in 0.05% Direct Red 80 (Sigma 365548, St. Louis, MO) in saturated picric acid for 90 minutes and washing in 0.01 N hydrochloric acid. For each section, 5-6 random images of the infarct area were scanned at 40X magnification. The image analysis was done on images that were 23 by 15 cm in size and enlarged on a 22 x 14 inch monitor, which allowed us to see the areas of positive stain using Image-Pro Plus 7.0 (MediaCybernetics, Inc. Rockville, MD).⁴ A second set of sections was used for immunohistochemistry using a rat anti-Mac-3 antibody (Cedarlane CL8943AP, Burlington, NC) to stain for macrophages. Slides were incubated in primary antibody overnight followed by incubation in secondary antibody and substrate, using the

Vectastain Elite ABC Kit (Vector Laboratories, Burlingame, CA) and the HistoMark Black Kit (KPL, Gaithersburg, MD), according to product protocols. Macrophage numbers were counted using Image using Image-Pro Plus 7.0. The negative control was an isotype matched control antibody. Representative images were scanned at 60X magnification.

Real Time PCR

Inflammatory, ECM, and adhesion molecule genes were evaluated for mRNA levels using the Inflammatory Cytokines and Receptors and the Extracellular Matrix and Adhesion Molecules arrays (Qiagen PAMM-011A and PAMM-013A, Valencia, CA). LV infarct (LVI) and LV control (LVC) tissue were homogenized separately in TRIzol reagent (Invitrogen, 15596-026, Grand Island, NY) and RNA was extracted according to the manufacturer's protocol. cDNA synthesis was carried out using RT² First Strand Kit (Qiagen 330401) and prepared for loading the array with SYBR Green qPCR Mastermix (Qiagen 330522). Results were normalized to 5 housekeeping genes (Gusb, Hprt1, HSP90ab1, Gapdh, Actb) and analyzed based on 2^{-ΔCt} values. None of these housekeeping genes were different among the groups evaluated.

Plasma Analysis

Blood was collected from the carotid artery by injecting the mouse with heparin (4 USP units per gram body weight) 5 min before sacrifice. Plasma was isolated by centrifugation at 2100 x g for 5 min, and then snap frozen and stored at -80°C.⁷ Samples (100 µl) were sent to Rules Based Medicine (Austin, TX) for the Rodent Multi-Analyte profiling (MAP). 58 different plasma analytes were quantified by a Clinical Laboratory Improvement Amendments (CLIA)-certified biomarker testing laboratory using reproducible, quantitative, multiplexed immunoassays.

Statistical and Data Analysis

All results are reported as mean±SEM. Statistical analyses were performed using statistical software JMP (Cary, NC), SAS (Cary, NC), or Graphpad's InStat (La Jolla, CA). Survival probability was analyzed with three methods: nonparametric tests, Cox regression models, and parametric survival models.⁸ The nonparametric tests used include log-rank and Wilcoxon tests that test the equality of two or more survival distributions. The nonparametric estimate was based on the Kaplan-Meier product-limit estimate⁹. The parametric survival model based on the best-fit probability distribution was used to estimate survival probability

curves and to test hypotheses concerning the effect of covariates on survival curve. Several parametric models were analyzed.¹⁰ The appropriateness of the distribution was checked using three criteria: a lowest corrected Akaike information criterion value, linearity of distribution plot, and residuals.¹¹ The Shapiro-Wilk test was used to test the echocardiographic data for normality, and the Bartlett and Kendall, O'Brien, Brown and Forsythe, and Levene tests were used to test residuals for equal variance and interaction factors.

A sparse singular value decomposition (SSVD) biclustering algorithm was applied to divide the gene levels in this study into sub-matrices¹⁴. Data matrices were categorized into sub-matrices consisting of cluster members (genes or proteins) and the cluster attributes (experimental conditions or phenotypes) that have high similarity scores according to the biclustering algorithm.¹² This algorithm used a measure of coherent relation of a cluster member and its attributes at the same time¹³. Several layers of the original data matrix were analyzed using SSVD under appropriate sparsity conditions. The sparsity conditions pushed the unimportant entries of the data matrix towards zero while keeping the decomposed matrix similar to the original one. The significant genes were then selected for each layer of the matrix.¹⁴ The original data was approximated by a summation of the sub-matrices.¹⁴ Each sub-matrix represented a layer of the original matrix, with respect to its significance to the original data matrix. Each layer of the matrix was also decomposed by its singular values.¹⁵

All other statistical comparisons were done with ANOVA and a Student-Newman Keuls post-test. A p<0.05 was considered significant.

Supplemental Table 1. ECM gene array results for WT remote (LVC) and infarct (LVI).
